

Project Design Phase Solution Architecture

Date	03 October 2026
Team ID	SWTID-2026-8726
Project Name	Auto Ticket Classification using FLOW DESIGNER
Maximum Marks	4 Marks

Solution Architecture:

The **Auto Ticket Classification using FLOW DESIGNER** solution bridges the service-desk problem of manual ticket triage with an automated ServiceNow workflow. The architecture defines how a newly created ticket is evaluated, classified, prioritized and routed to the appropriate support group.

The solution consists of the following major processes:

- **Ticket Creation** – A new Incident / Service Request is created.
- **Flow Trigger** – Flow Designer starts automatically when the ticket satisfies the configured trigger condition.
- **Content Evaluation & Parsing** – Ticket description, keywords, requester profile and channel source are evaluated.
- **Decision Matrix & Conditional Branching** – Configured classification conditions determine the appropriate category, priority and assignment group.
- **Automatic Assignment** – The ticket is routed to the relevant support team.
- **Fallback Handling** – Unmatched or ambiguous tickets are sent to the General Support Triage Queue for manual review.
- **Logging & Audit** – Classification decisions, assignment actions and errors are recorded.

This follows the project's documented architecture of **Trigger & Event Ingestion** → **Content Evaluation & Parsing** → **Decision Matrix & Conditional Branching** → **Assignment/Processing**.

Solution Architecture & Data Flow
