

Auto Ticket Classification using FLOW DESIGNER

Project Documentation

Project Title	Auto Ticket Classification using FLOW DESIGNER
Team ID	SWTID-2026-8726
Date	03 October 2026

1. Introduction

• Project Title

Auto Ticket Classification using FLOW DESIGNER

• Team Members

Team ID: SWTID-2026-8726. Individual team member names and roles were not provided in the available project material.

2. Project Overview

• Purpose

The purpose of the project is to automate the initial classification, prioritization and routing of ServiceNow Incident / Service Request tickets using Flow Designer. The workflow reduces dependency on manual triage and provides a consistent process for assigning category, priority and assignment group.

• Features

- Record-created Flow Designer trigger.
- Evaluation of ticket description, keywords, requester profile and channel source.
- Rule-based category classification.
- Automatic P1–P4 priority assignment based on configured conditions.
- Automatic assignment-group routing.
- Fallback handling through a General Support Triage Queue for unmatched tickets.
- Workflow/system logging and audit records.

3. Architecture

• Platform / Workflow Architecture

The project is implemented as a ServiceNow Flow Designer workflow. A newly created Incident or Service Request enters the workflow, where content is evaluated and decision logic determines category, priority and assignment group.

• Workflow Components

- Ticket / Incident / Service Request record.
- Flow Designer Record Created trigger.
- Content Evaluation & Parsing.
- Decision Matrix & Conditional Branching.

- Category, Priority and Assignment Group actions.
- Support groups such as NOC, Helpdesk, Systems Engineering and HR Operations, according to configured rules.
- General Support Triage Queue for unmatched tickets.
- System Logs / Audit Records.

• **Data / Record Interaction**

The workflow reads ticket details and relevant requester information, evaluates configured rules, and updates the ticket with classification, priority and assignment information. The project documentation does not specify a separate external database schema.

4. Setup Instructions

• **Prerequisites**

- Access to the configured ServiceNow instance.
- Appropriate ServiceNow permissions for Flow Designer and ticket records.
- Configured Incident / Service Request data and assignment groups.
- Configured classification keywords and conditional routing rules.

• **Installation / Configuration**

- Open the ServiceNow application environment.
- Configure or verify the Incident / Service Request record structure.
- Create the Flow Designer Record Created trigger.
- Configure content evaluation and classification conditions.
- Configure category, priority and assignment-group actions.
- Configure the General Support Triage Queue fallback.
- Configure logging / audit requirements.
- Activate and test the flow with representative tickets.

5. Folder Structure

A conventional source-code folder structure is not specified for this ServiceNow Flow Designer project. The logical project structure is organized around ServiceNow records, Flow Designer flows, conditions, assignment groups and audit/logging configuration.

- Ticket Records – Incident / Service Request data.
- Flow Designer – Trigger, actions and conditional branches.
- Classification Rules – Keywords and configured conditions.
- Assignment Groups – Support-team routing configuration.
- Fallback Queue – General Support Triage.
- Logs / Audit – Workflow execution and audit information.

6. Running the Application

The solution runs inside the configured ServiceNow environment. There are no local frontend/backend npm commands specified in the available project material.

- Open the ServiceNow ticketing interface.
- Create an Incident or Service Request.
- Submit/save the ticket.
- Allow the configured Flow Designer trigger to execute.
- Verify category, priority and assignment group.
- Review fallback handling and logs when applicable.

7. API Documentation

No external REST API endpoints are specified in the available project documentation. The current implementation is based on ServiceNow Flow Designer and record/workflow actions.

8. Authentication

Authentication and authorization are handled by the ServiceNow platform and the permissions/roles configured for the application environment. Specific usernames, passwords, tokens or role mappings were not provided in the available project material.

9. User Interface

The user interacts with the ServiceNow ticketing interface to create and view Incident / Service Request records. The automated workflow operates behind the ticket interface and updates classification, priority and assignment information.

- Ticket creation interface – insert screenshot.
- Classified ticket with category and priority – insert screenshot.
- Assignment Group result – insert screenshot.
- Flow Designer workflow – insert screenshot.

10. Testing

Testing covers ticket creation and triggering, content evaluation, classification, priority assignment, assignment-group routing, fallback handling, audit logging and end-to-end workflow execution.

- Functional testing – positive and negative ticket scenarios.
- Performance testing – triage response time and routing performance.
- UAT – end-user acceptance of classification and routing behavior.
- Documented routing accuracy: 96.8%.
- Documented average triage time: 1.2 seconds.
- Documented SLA compliance: 98.5%.

11. Screenshots or Demo

The final documentation should include screenshots of the Flow Designer workflow, ticket creation, automatically classified ticket, priority/assignment result, fallback queue and workflow execution/audit output.

Project Demo Link: To be added by the project team, if available.

12. Known Issues

- Unmatched or ambiguous tickets may require manual review through the General Support Triage Queue.
- Rule-based classification depends on the configured keywords and conditions.
- Changes in ticket terminology or routing requirements require rule maintenance.
- The current implementation does not specify a machine-learning model.

13. Future Enhancements

- Machine Learning Integration for semantic ticket classification.
- Sentiment Analysis for escalation and prioritization.
- Multi-Language Support.
- Dynamic Load Balancing based on support-team workload.
